

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

# OF INDUCTION,

WITH ESPECIAL REFERENCE TO

[R. J. STUART MILL'S SYSTEM OF LOGIC.

*William*

BY W. WHEWELL, D.D.,

AUTHOR OF THE HISTORY AND THE PHILOSOPHY OF THE  
INDUCTIVE SCIENCES.

Λαμπάδια ἔχοντες διαδώσουσιν ἀλλήλοις.

Ὡ LONDON :

JOHN W. PARKER, WEST STRAND.

---

Works on Induction.

Occasion of this Work.

I confine myself to physical science.

Mr Mill's definition of Induction.

How far I assent to it.

I dissent as to induction of particulars.

Mr Mill extends induction to practice,

And to brutes.

Holds ideas necessary to action.

Remark on this.

This does not describe *human* knowledge.

Induction is applicable to generals only.

This difference is necessary.

Practical skill is not included in Induction.

General terms requisite in Induction.

Mr Mill reckons superstitious belief as Induction.

I reject these.

Mr Mill denies Kepler's ellipse to be an induction.

My reply.

What is the difference of Induction and Description?

"The ellipse is a *fact*."

The word "fact" is no argument.

Can different inductions coincide?

Yes.

Superstitious inductions.

Even these mark no difference of Induction and Description.

- 27 A conception was introduced by Kepler,
- 28 And is introduced in all induction.
- 29 This exemplified in the *Philosophy*,
- 30 Is proved by scientific controversies,
- 31 And by the new term in each discovery.
- 32 Mr Mill denies the conception.
- 33 Remark on this.
- 34 Mr Mill wrong in denying conceptions.
- 35 Mr Mill on names of conceptions.
- 36 It is the mind that sees.
- 37 Idea of Polarity slowly evolved.
- 38 Discussions of Definitions useful.
- 39 Mr Mill's mode of expression.
- 40 How far adequate.
- 41 Mr Mill's four Methods of Inquiry.
- 42 Remarks on these Methods.
- 43 Herschel's remark on Bacon's Instances.
- 44 Mr Mill's examples of his Methods
- 45 Are many of them taken from Liebig.
- 46 Mr Bain's view of Electricity.
- 47 Wells on Dew.
- 48 Arago's copper disk.
- 49 Weight of compound equal weights of elements.
- 50 Incomplete examples.
- 51 Examples from mental science.
- 52 Reply to Mr Mill on hypotheses.  
Note on a Natural Series.
- 53 Analogy and Identity.
- 54 Confirmation of hypothesis by prediction.
- 55 Consilience of inductions.
- 56 Hypotheses which may be verified.  
Note on M. Comte's *Philosophie Positive*.
- 57 Newton's Rule of *vera causa*.
- 58 Methods given by Mr Whewell.
- 59 Bacon on successive generalization.

- 0 Mr Mill notices generalization as *subsumption*.
  - 1 Holds Bacon to be wrong on this subject.
  - 2 Bacon confirmed by the History of Astronomy and  
Optics,
  - 3 And of Mechanics.
  - 4 Case of Hydrostatics.
  - 5 Reasons for Bacon's maxim given by Mr Mill.
  - 6 Mr Mill's hopes from Deduction.
  - 7 Not tenable for the material sciences.
  - 8 Danger of despairing of Induction.
  - 9 Deduction recommended by explanation of Facts,
  - 0 And by its office in speculations on mind.
  - 1 Are Axioms derived from experience?
  - 2 This question not here discussed.
  - 3 Mr Mill on Fallacies.
  - 4 Difficulties on Mr Whewell's side.
  - 5 Difficulties on Mr Mill's side.
  - 6 His opinion of copies in the mind.
  - 7 Conclusion. Mr Mill's merits.
-

**OF INDUCTION.**

**OF INDUCTION.**

saying, or thinking, that there is no such thing as Moral and Political Science, or that no method can be suggested for its promotion; but I think that by attempting at present to include the Moral Sciences in the same formulæ with the Physical, we open far more controversies than we close; and that in the moral as in the physical sciences, the first step towards shewing how truth is to be discovered, is to study some portion of it which is assented to so as to be beyond controversy.

4 Confining myself, then, to the material sciences, I shall proceed to offer my remarks on Induction with especial reference to Mr Mill's work. And in order that we may, as I have said, proceed as intelligibly as possible, let us begin by considering what we mean by *Induction*, as a mode of obtaining truth; and let us note whether there is any difference between Mr Mill and me on this subject.

"For the purposes of the present inquiry," Mr Mill says (i. 347\*), "Induction may be defined the operation of discovering and forming general propositions:" meaning, as appears by the context, the discovery of them from particular facts. He elsewhere (i. 370) terms it "generalization from experience:" and again

\* My references are throughout (except when otherwise expressed) to the volume and the page of Mr. Mill's first edition of his *Logic*.

he speaks of it with greater precision as the inference of a more general proposition from less general ones.

5 Now to these definitions and descriptions I assent as far as they go; though, as I shall have to remark, they appear to me to leave unnoticed a feature which is very important, and which occurs in all cases of Induction, so far as we are concerned with it. Science, then, consists of general propositions, inferred from particular facts, or from less general propositions, by Induction; and it is our object to discern the nature and laws of Induction in this sense. That the propositions are general, or are more general than the facts from which they are inferred, is an indispensable part of the notion of Induction, and is essential to any discussion of the process, as the mode of arriving at Science, that is, at a body of general truths.

6 I am obliged therefore to dissent from Mr Mill when he includes, in his notion of Induction, the process by which we arrive at *individual facts* from other facts *of the same order of particularity*.

Such inference is, at any rate, not Induction *alone*; if it be Induction at all, it is Induction applied to an example.

For instance, it is a general law, obtained by Induction from particular facts, that a body

falling vertically downwards from rest, describes spaces proportional to the squares of the times. But that a particular body will fall through 16 feet in one second and 64 feet in two seconds, is not an induction simply, is a result obtained by applying the inductive law to a particular case.

But further, such a process is often not induction *at all*. That a ball striking another ball directly will communicate to it as much momentum as the striking ball itself loses, is a law established by induction: but if, from habit or practical skill, I make one billiard ball strike another, so as to produce the velocity which I wish, without knowing or thinking of the general law, the term *Induction* cannot then be rightly applied. If I *know the law* and act upon it, I have in my mind both the general induction and its particular application. But if I act by the ordinary billiard player's skill, without thinking of momentum or law, there is no Induction in the case.

7 This distinction becomes of importance, in reference to Mr Mill's doctrine, because he has extended his use of the term *Induction*, not only to the cases in which the general induction is consciously applied to particular instance; but to the cases in which the particular instance is dealt with by means of experience, in that rude sense in which

*perience* can be asserted of brutes; and in which, of course, we can in no way imagine that the law is possessed or understood, as a general proposition. He has thus, as I conceive, overlooked the broad and essential difference between speculative knowledge and practical action; and has introduced cases which are quite foreign to the idea of science, alongside with cases from which we may hope to obtain some views of the nature of science and the processes by which it must be formed.

8 Thus (ii. 232) he says, "This inference of one particular fact from another is a case of induction. It is of this sort of induction that brutes are capable." And to the same purpose he had previously said, (i. 251) "He [the burnt child who shuns the fire] is not generalizing: he is inferring a particular from particulars. In the same way also, brutes reason ...not only the burnt child, but the burnt dog, dreads the fire."

9 This confusion, (for such it seems to me,) of knowledge with practical tendencies, is expressed more in detail in other places. Thus he says (i. 118) "I cannot dig the ground unless I have an idea of the ground and of a spade, and of all the other things I am operating upon."

10 This appears to me to be a use of words which can only tend to confuse our idea of

knowledge by obliterating all that is distinctive in *human* knowledge. It seems to me quite false to say that I cannot dig the ground, unless I have an idea of the ground and of my spade. Are we to say that we cannot *walk* the ground, except we have an idea of the ground, and of our feet, and of our shoes, and of the muscles of our legs? Are we to say that a mole cannot dig the ground, except he has an idea of the ground and of the snout and paws with which he digs it? Are we to say that a pholas cannot perforate a rock, except he have an idea of the rock, and of the acid with which he corrodes it?

11 This appears to me, as I have said, to be a line of speculation which can lead to nothing but confusion. The knowledge concerning which I wish to inquire is *human* knowledge. And in order that I may have any chance of success in the inquiry, I find it necessary to single out that kind of knowledge which is especially and distinctively human. Hence, I pass by, in this part of my investigation, all the *knowledge*, if it is to be so called, which man has in no other way than brutes have it;—all that merely shews itself in action. For though action may be modified by habit, and habit by experience, in animals as well as in men, such experience, so long as it retains that merely practical

form, is no part of the materials of science. Knowledge in a *general* form, is alone knowledge for that purpose; and to *that*, therefore, must confine my attention; at least till I have made some progress in ascertaining its nature and laws, and am thus prepared to compare such knowledge,—*human knowledge* properly so called,—with mere animal tendencies to action; or even with practical skill which does not include, as for the most part practical skill does not include, speculative knowledge.

12 And thus, I accept Mr Mill's definition of Induction only in its first and largest form; and reject, as useless and mischievous for our purposes, his extension of the term to the practical influence which experience of one object exercises upon a creature dealing with similar facts. Such influence cannot be resolved into *ideas* and *induction*, without, as I conceive, making all our subsequent investigation vague and heterogeneous, indefinite and conclusive. If we must speak of animals as *learning* from experience, we may at least abstain from applying to them terms which imply that they learn, in the same way in which men learn astronomy from the stars, and chemistry from the effects of mixture and heat. And the same may be said of the language which is to be used concerning what *men* learn, when

their *learning* merely shews itself in action and does not exist as a general thought.

✓ *Induction* must not be applied to such cases. *Induction* must be confined to cases in which we have in our minds general propositions, in order that the sciences, which are our most instructive examples of the process we have to consider, may be, in any definite and proper sense, Inductive Sciences.

13 Perhaps some persons may be inclined to say that this difference of opinion as to the extent of meaning which is to be given to the term *Induction*, is a question merely of words; a matter of definition or definition. This is a mode in which men in our times often seem inclined to dispose of philosophical questions; thus evading the task of forming an opinion upon such questions, while they retain the air of looking at the subject from a more comprehensive point of view. But as we have elsewhere said, such questions of definition are never questions of definition merely. A proposition is always implied along with a definition; and the truth of the proposition depends upon the settlement of the definition. This is the case in the present instance. When we are speaking of *Induction*, and we mean that kind of Induction by which the sciences now existing among men have been constructed, on this account it is, that we cannot include,

the meaning of the term, mere practical tendencies or practical habits; for science is not constructed of these. No accumulation of these would make up any of the acknowledged sciences. The elements of such sciences are something of a kind different from practical habits. The elements of such sciences are principles which we *know*; truths which can be contemplated as being *true*. Practical habits, practical skill, instincts and the like appear in action, and in action only. Such endowments or acquirements shew themselves when the occasion for action arrives, and then, shew themselves in the act; without being put, or being capable of being put, in the form of truths contemplated by the intellect. || But the elements and materials of Science are necessary truths contemplated by the intellect. <sup>16</sup> It is by consisting of such elements and such materials, that Science is Science. Hence a use of the term *Induction* which requires us to obliterate this distinction, must make it impossible for us to arrive at any consistent and intelligible view of the nature of science, and of the mental process by which sciences come into being. We must, for the purpose which Mr Mill and I have in common, retain his larger and more philosophical definition of Induction, that it is the inference of a more general proposition from less general ones.

14 Perhaps, again, some persons may say that practical skill and practical experience *lead to* science, and may therefore be included in the term *Induction*, which describes the formation of science. But to this we reply that these things lead to science as occasions only, and do not form part of science; and that science begins then only when we look at the facts in a general point of view. This distinction is essential to the philosophy of science. The rope-dancer may, by his performances, suggest, to himself or to others, the properties of the center of gravity; but this is so, because man has a tendency to speculate and to think of general truths, as well as a tendency to dance on a rope on special occasions, and to acquire skill in such dancing by practice. The rope-dancer does not dance by Induction, any more than the dancing-dog does. To apply the terms Science and Induction to such cases, carries us into the region of metaphor; as when we call birds of passage "wise meteorologists," or the bee "a natural chemist, who turns the flower-dust into honey." This is very well in poetry: but for our purposes we must avoid recognizing these cases as really belonging to the sciences of meteorology and chemistry,—as really cases of Induction. Induction for us is general propositions, *contemplated as such*, derived from particulars.

Science may result *from* experience and observation *by* Induction; but Induction is not therefore the same thing as experience and observation. Induction is experience or observation *consciously* looked at in a *general* form. This consciousness and generality are necessary parts of that knowledge which is science. And accordingly, on the other hand, science cannot result from mere Instinct, as distinguished from Reason; because Instinct by its nature is not conscious and general, but operates blindly and unconsciously in particular cases, the actor not seeing nor thinking of the rule which he obeys.

15 A little further on I shall endeavour to shew that not only a general *thought*, but a general *word* or phrase is a requisite element in Induction. This doctrine, of course, still more decidedly excludes the case of animals, and of mere practical knowledge in man. A burnt child dreads the fire; but reason must be unfolded before the child learns to understand the words "fire will hurt you." The burnt dog never thus learns to understand words. And this difference points to an entirely different state of thought in the two cases: or rather, to a difference between a state of rational thought on the one hand, and of mere practical instinct on the other.

16 Besides this difference of speculative

thought and practical instinct which thus are as appears to me, confounded in Mr Mill's philosophy, in such a way as tends to destroy all coherent views of human knowledge, there is another set of cases to which Mr Mill applies the term *Induction*, and to which it appears to me to be altogether inapplicable. He employs it to describe the mode in which superstitious men, in ignorant ages, were led to the opinion that striking natural events presaged or accompanied calamities. Thus he says (i. 389) "The opinion so long prevalent that a comet or any other unusual appearance in the heavenly regions was the precursor of calamities to mankind, or at least to those who witnessed it; the belief in the oracles of Delphi and Dodona; the reliance on astrology or on the weather-prophecies in almanacs were doubtless inductions supposed to be grounded on experience;" and he speaks of these insufficient inductions being extinguished by the stronger inductions subsequently obtained by scientific inquiry. And in like manner, he says in another place (i. 367) "Let us now compare different predictions: the first that eclipses will occur whenever one planet or satellite is so situated as to cast its shadow upon another: the second, that they will occur whenever some great calamity is impending over mankind."

17 Now I cannot see how anything but confusion can arise from applying the term *Induction* to superstitious fancies like those here mentioned. They are not imperfect truths, but entire falsehoods. Of that, Mr Mill and I are agreed: how then can they exemplify the progress towards truth? They were not collected from the facts by seeking a law of their occurrence; but were suggested by an imagination of the anger of superior powers shown by such deviations from the ordinary course of nature. If we are to speak of *inductions* to any purpose, they must be such inductions as represent the facts, in some degree at least. It is not meant, I presume, that these opinions are in any degree true: to what purpose then are they adduced? If I were to hold that my dreams predict or conform to the motions of the stars or of the clouds, would this be an induction? It would be so, as much one as those here so denominated: what but confusion could arise from classing it among scientific truths? Mr Mill himself has explained (ii. 389) the way in which such delusions as the prophecies of almanac-makers, and the like, obtain credence; namely, the greater effect which the positive instances produce on ordinary minds in comparison of the negative, when the rule has once taken possession of their thoughts. And

this being, as he says, the recognized explanation of such cases, why should we not leave them to their due place, and not confound and perplex the whole of our investigation by elevating them to the rank of "inductions?" The very condemnation of such opinions is that they are not at all inductive. When we have made any progress in our investigation of the nature of science, to attempt to drive us back to the wearisome discussion of such elementary points as these is to make progress hopeless.

18 In the cases hitherto noticed, Mill extends the term *Induction*, as I think too widely, and applies it to cases to which it is not rightly applicable. I have now to notice a case of an opposite kind, in which he does not apply it where I do, and condemns me for using it in such a case. I had spoken of Kepler's discovery of the Law, that the planets move round the sun in ellipses, as an example of Induction. The separate facts of a planet (Mars, for instance,) being in certain places at certain times, are all included in the general proposition which Kepler discovered, that Mars describes an ellipse of certain form and position. This appears to me a very simple but a very distinct example of the operation of discovering general propositions; general, that is, with reference

articular facts; which operation Mr Mill, as well as myself, says is Induction. But Mr Mill denies this operation in this case to be Induction at all (i. 357). I should not have been prepared for this denial by the previous parts of Mr Mill's book, for he had said just before (i. 350), "Such facts as the magnitudes of the bodies of the solar system, their distances from each other, the figure of the earth and its rotation ... are proved indirectly, by the aid of inductions founded on other facts which we can more easily reach." If the figure of the earth and its rotation are proved by Induction, it seems very strange, and is to me quite incomprehensible, how the figure of the earth's orbit and its revolution (and of course, of the figure of Mars's orbit and his revolution in like manner,) are not also proved by Induction. No, says Mr Mill, Képler, in putting together a number of places of the planet into one figure, only performed an act of description. "This descriptive operation," he adds (i. 359), "Mr Whewell, by an aptly chosen expression, has termed Colligation of Facts." He goes on to commend my observations concerning this process, but says that, according to the old and received meaning of the term, it is not Induction at all.

19 Now I have already shewn that Mr Mill himself, a few pages earlier, had applied

the term *Induction* to cases undistinguishable from this in any essential circumstance. And even in this case, he allows that Kepler did really perform an act of Induction (i. 358), "namely, in concluding that, because the observed places of Mars were correctly represented by points in an imaginary ellipse, therefore Mars would continue to revolve in that same ellipse; and even in concluding that the position of the planet during the time which had intervened between the two observations must have coincided with the intermediate points of the curve." Of course, in Kepler's Induction, of which I speak, I include all this; all this is included in speaking of the *orbit* of Mars: a continuous line, a periodical motion, are implied in the term *orbit*. I am unable to see what would remain of Kepler's discovery, if we take from it these conditions. It would not only not be an induction, but it would not be a description, for it would not recognise that Mars moved in an orbit. Are particular positions to be conceived as points in a curve, without thinking of the intermediate positions as belonging to the same curve? If so, there is no law at all, and the facts are not bound together by any intelligible tie.

In another place (ii. 209) Mr Mill returns to his distinction of Description and Induction;

ut without throwing any additional light upon  
i, so far as I can see.

20 The only meaning which I can discover in this attempted distinction of Description and Induction is, that when particular facts are bound together by their relation in *space*, Mr Mill calls the discovery of the connection *Description*, but when they are connected by other general relations, as time, cause and the like, Mr Mill terms the discovery of the connection *Induction*. And this way of making a distinction, would fall in with the doctrine of other parts of Mr Mill's book, in which he ascribes very peculiar attributes to space and its relations, in comparison with other Ideas, as I should call them). But I cannot see any ground for this distinction, of connection according to space and other connections of facts.

To stand upon such a distinction, appears to me to be the way to miss the general laws of the formation of science. For example: The ancients discovered that the planets revolved in recurring periods, and thus connected the observations of their motions according to the Idea of *Time*. Kepler discovered that they revolved in ellipses, and thus connected the observations according to the Idea of *Space*. Newton discovered that they revolved in virtue of the Sun's attraction, and thus connected the

motions according to the Idea of *Force*. The first and third of these discoveries are recognised on all hands as processes of Induction. Why is the second to be called by a different name? or what but confusion and perplexity can arise from refusing to class it with the other two? It is, you say, Description. But such Description is a kind of Induction, and must be spoken of as Induction, if we are to speak of Induction as the process by which Science is formed: for the three steps are all, the second in the same sense as the first and third, in co-ordination with them, steps in the formation of astronomical science.

21 But, says Mr Mill, (i. 363) "it is a fact surely that the planet does describe an ellipse, and a fact which we could see if we had adequate visual organs and a suitable position." To this I should reply: "Let it be so; and it is a fact, surely, that the planet does move periodically: it is a fact, surely, that the planet is attracted by the sun. Still, therefore, the asserted distinction fails to find a ground." Perhaps Mr Mill would remind us that the elliptical form of the orbit is a fact which we could see if we had adequate visual organs and a suitable position: but that force is a thing which we cannot see. But this distinction also will not bear handling. Can we not see a tree blown down by a storm, or a rock

blown up by gunpowder? Do we not here see force:—see it, that is, by its effects, the only way in which we need to see it in the case of a planet, for the purposes of our argument? Are not such operations of force, Facts which may be the objects of sense? and is not the operation of the sun's Force a Fact of the same kind, just as much as the elliptical form of orbit which results from the action? If the latter be “surely a Fact,” the former is a Fact no less surely.

22 In truth, as I have repeatedly had occasion to remark, all attempts to frame an argument by the exclusive or emphatic appropriation of the term *Fact* to particular cases, are necessarily illusory and inconclusive. There is no definite and stable distinction between facts and Theories; Facts and Laws; Facts and Inductions. Inductions, Laws, Theories, which are true, *are* Facts. Facts involve Inductions. It is a Fact that the moon is attracted by the earth, just as much as it is a Fact that an apple falls from a tree. That the former fact is collected by a more distinct and conscious Induction, does not make it the less a Fact. That the orbit of Mars is a Fact—a true Description of the path—does not make the less a case of Induction.

23 There is another argument which Mr Mill employs in order to shew that there

is a difference between mere colligation which is description, and induction in the more proper sense of the term. He notices with commendation a remark which I had made (i. 364) that at different stages of the progress of science the facts had been successfully connected by means of very different conceptions while yet the later conceptions have not contradicted, but included, so far as they were true, the earlier: thus the ancient Greek representation of the motions of the planets by means of epicycles and eccentrics, was to a certain degree of accuracy true, and is not negatived, though superseded, by the modern representation of the planets as describing ellipses round the sun. And he then reasons that this, which is thus true of Descriptions cannot be true of Inductions. He says (i. 367) "Different descriptions therefore may be all true: but surely not different explanations." He then notices the various explanations of the motions of the planets—the ancient doctrine that they are moved by an inherent virtue the Cartesian doctrine that they are moved by impulse and by vortices; the Newtonian doctrine that they are governed by a central force and he adds, "Can it be said of these, as was said of the different descriptions, that they are all true as far as they go? Is it not true that one only can be true in any degree

and that the other two must be altogether false?"

24 And to this questioning, the history of science compels me to reply very distinctly and positively, in the way which Mr Mill appears to think extravagant and absurd. I am obliged to say, Undoubtedly, all these explanations *may* be true and consistent with each other, and would be so if each had been followed out so as to shew in what manner it could be made consistent with the facts. And this was, in reality, in a great measure done. The doctrine that the heavenly bodies were moved by vortices was successively modified, so that it came to coincide in its results with the doctrine of an inverse-quadratic centripetal force, as I have remarked in the *History*, (B. VII. c. iii. sect. 3). When this point was reached, the vortex was merely a machinery, well or ill devised, for producing such a centripetal force, and therefore did not contradict the doctrine of a centripetal force. Newton himself does not appear to have been averse to explaining gravity by impulse. So little is it true that if one theory be true the other must be false. The attempt to explain gravity by the impulse of streams of particles flowing through the universe in all directions, which I have mentioned in the *Philosophy*, (B. III. c. ix. art. 7), is so far from being in-

consistent with the Newtonian theory, that it is founded entirely upon it. And even with regard to the doctrine, that the heavenly bodies move by an inherent virtue; if this doctrine had been maintained in any such way that it was brought to agree with the facts, the inherent virtue must have had its laws determined; and then, it would have been found that the virtue had a reference to the central body; and so, the "inherent virtue" must have coincided in its effect with the Newtonian force; and then, the two explanations would agree, except so far as the word "inherent" was concerned. And if such a part of an earlier theory as this word *inherent* indicates, is found to be untenable, it is of course rejected in the transition to later and more exact theories, in Inductions of this kind, as well as in what Mr Mill calls Descriptions. There is therefore still no validity discoverable in the distinction which Mr Mill attempts to draw between "descriptions" like Kepler's law of elliptical orbits, and other examples of induction.

25 When Mr Mill goes on to compare what he calls different predictions—the first, the true explanation of eclipses by the shadows which the planets and satellites cast upon one another, and the other, the belief that they will occur whenever some great

calamity is impending over mankind, I must reply, as I have stated already, (Art. 17), that no class such superstitions as the last with cases of Induction, appears to me to confound all use of words, and to prevent, as far as it goes, all profitable exercise of thought. What possible advantage can result from comparing (as if they were alike) the relation of two descriptions of a phenomenon, each to a certain extent true, and therefore both consistent, with the relation of a scientific truth to a false and baseless superstition?

26 But I may make another remark on this example, so strangely introduced. 'If, under the influence of fear and superstition, men may make such mistakes with regard to laws of nature, as to imagine that eclipses portend calamities, are they quite secure from mistakes in *description*? Do not the very persons who tell us how eclipses predict disasters, also describe to us fiery swords seen in the air, and armies fighting in the sky? So that even in this extreme case, at the very limit of the rational exercise of human powers, there is nothing to distinguish Description from Induction.

I shall now leave the reader to judge whether this feature in the history of science,—that several views which appear at first quite different are yet all true,—which Mr

Mill calls a curious and interesting remark mine, and which he allows to be "strikingly true" of the Inductions which he calls *Descriptions*, (i. 364) is, as he says, "unequivocally false" of other Inductions. And I shall confide in having general assent with me, when I continue to speak of Kepler's *Induction* of elliptical orbits.

I now proceed to another remark.

27 There is a difference between Mr Mill and me in our view of the essential elements of this Induction of Kepler, which affects other cases of Induction, and which is, I think, the most extensive and important of the differences between us. I must therefore venture to dwell upon it a little in detail.

X / I conceive that Kepler, in discovering the law of Mars's motion, and in asserting that the planet moved in an ellipse, did this;—bound together particular observations of separate places of Mars by the notion, or, I have called it, the *conception*, of an *ellipse*, which was supplied by his own mind. Other persons, and he, before he made this discovery, had present to their minds the figure of such separate successive positions of the planet; but could not bind them together rightly, because they did not apply to this conception of an *ellipse*. To supply this conception, required a special preparation,

special activity in the mind of the discoverer. He, and others before him, tried other ways of connecting the special facts, none of which fully succeeded. To discover such a connection, the mind must be conversant with certain relations of space, and with certain kinds of figures. To discover the right figure was a matter requiring research, invention, resource. To hit upon the right conception is a difficult step; and when this step is once made, the facts assume a different aspect from what they had before: that done, they are seen in a new point of view; and the catching this point of view, is a special mental operation, requiring special endowments and habits of thought. Before this, the facts are seen as detached, separate, lawless; afterwards, they are seen as connected, simple, regular; as parts of one general fact, and thereby possessing innumerable new relations before unseen. Kepler, then, say, bound together the facts by super-inducing upon them the *conception* of an *ellipse*, and this was an essential element in his Induction.)

28 And there is the same essential element in all Inductive discoveries. In all cases, facts, before detached and lawless, are bound together by a new thought. They are reduced to law, by being seen in a new point of view.

To catch this new point of view, is an act of the mind, springing from its previous preparation and habits. The facts, in other discoveries, are brought together according to other relations, or, as I have called them *Ideas*;—the Ideas of Time, of Force, of Number, of Resemblance, of Elementary Composition, of Polarity, and the like. But in all cases the mind performs the operation by an apprehension of some such relations; by singling out the one true relation; by combining the apprehension of the true relation with the facts; by applying to them the Conception of such a relation.

29 In previous writings, I have not only stated this view generally, but I have followed it into detail, exemplifying it in the greater part of the History of the principal Inductive Sciences in succession. I have pointed out what are the Conceptions which have been introduced in every prominent discovery in those sciences; and have noted to which of the above Ideas, or of the like Ideas, each belongs. The performance of this task is the office of the greater part of my *Philosophy of the Inductive Sciences*. For that work is, in reality no less historical than the *History* which preceded it. The *History of the Inductive Sciences* is the history of the discoveries, mainly so far as concerns the *Facts* which were brought to

gether to form sciences. The *Philosophy* is, in the first ten Books, the history of the *Ideas* and *Conceptions*, by means of which the facts were connected, so as to give rise to scientific truths. It would be easy for me to give a long list of the *Ideas* and *Conceptions* thus brought into view, but I may refer any reader who wishes to see such a list, to the Tables of Contents of the *History*, and of the first ten Books of the *Philosophy*.

30 That these *Ideas* and *Conceptions* are really distinct elements of the scientific truths thus obtained, I conceive to be proved beyond doubt, not only by considering that the discoveries never were made, nor could be made, till the right *Conception* was obtained, and by seeing how difficult it often was to obtain this element; but also, by seeing that the *Idea* and the *Conception* itself, as distinct from the *Facts*, was, in almost every science, the subject of long and obstinate controversies;—controversies which turned upon the possible relations of *Ideas*, much more than upon the actual relations of *Facts*. The first ten Books of the *Philosophy* to which I have referred, contain the history of a great number of these controversies. These controversies make up a large portion of the history of each science; a portion quite as important as the study of the facts; and a portion, at every

stage of the science, quite as essential to the progress of truth. Men, in seeking and obtaining scientific knowledge, have always shewn that they found the formation of right conceptions in their own minds to be an essential part of the process.

II. Moreover, the presence of a Conception of the mind as a special element of the inductive process, and as the tie by which the particular facts are bound together, is further indicated, by there being some special new term or phrase introduced in every induction; or at least some term or phrase thenceforth steadily applied to the facts, which had not been applied to them before; as when Kepler asserted that Mars moved round the sun in an *elliptical orbit*, or when Newton asserted that the planets *gravitate* towards the sun; these new terms *elliptical orbit*, and *gravitate*, mark the new conceptions on which the inductions depend. I have in the *Philosophy* (B. I. c. iii.) further illustrated this application of "technical terms" that is, fixed and settled terms, in every inductive discovery; and have spoken of their use in enabling men to proceed from each such discovery to other discoveries more general. But I notice these terms here, for the purpose of shewing the existence of a conception in the discoverer's mind, corresponding to the term thus introduced; which

ception, the term is intended to convey the minds of those to whom the discovery communicated.

32 But this element of discovery,—right conceptions supplied by the mind in order to add the facts together,—Mr Mill denies to be an element at all. He says, of Kepler's discovery of the elliptical orbit, (i. 363) "It superadded nothing to the particular facts which served to bind together;" yet he adds, except indeed the knowledge that a resemblance existed between the planetary orbit and other ellipses;" that is, except the knowledge that it *was* an ellipse;—precisely the circumstance in which the discovery consisted. Kepler, he says, "asserted as a fact that the planet moved in an ellipse. But this fact, which Kepler did not add to, but found in the motion of the planet...was the very fact, the separate parts of which had been separately served; it was the sum of the different observations."

33 That the fact of the elliptical motion is not merely the *sum* of the different observations, is plain from this, that other persons, and Kepler himself before his discovery, did not find it by adding together the observations. The fact of the elliptical orbit was not the sum of the observations *merely*; it was the sum of the observations, *seen under*

*a new point of view*, which point of view Kepler's mind supplied. Kepler found it in the facts, because it was there, no doubt, for one reason ; but also, for another, because he had, in his mind, those relations of thought which enabled him to find it. We may illustrate this by a familiar analogy. We too find the law in Kepler's book ; but if we did not understand Latin, we should not find it there. We must learn Latin in order to find the law in the book. In like manner, a discoverer must know the language of science, as well as look at the book of nature, in order to find scientific truth. All the discussions and controversies respecting Ideas and Conceptions of which I have spoken, may be looked upon as discussions and controversies respecting the grammar of the language in which nature speaks to the scientific mind. Man is the Interpreter of Nature; not the Spectator merely, but the Interpreter. The study of the language, as well as the mere sight of the characters, is requisite in order that we may read the inscriptions which are written on the face of the world. And this study of the language of nature, that is, of the necessary coherencies and derivations of the relations of phenomena, is to be pursued by examining Ideas, as well as mere phenomena ;—by tracing the formation of Conceptions, as well as the accumulation of

Facts. And this is what I have tried to do in the books already referred to.

34 Mr Mill has not noticed, in any considerable degree, what I have said of the formation of the Conceptions which enter into the various sciences; but he has, in general terms, denied that the Conception is anything different from the facts themselves. "If," he says, (i. 301) "the facts are rightly classed under the conceptions, it is because there is in the facts themselves, something of which the conception is a copy." But it is a copy which cannot be made by a person without peculiar endowments; just as a person cannot copy an ill-written inscription, so as to make it convey sense, except he understand the language. "Conceptions," Mr Mill says, (ii. 217) "do not develope themselves from within, but are impressed from without." But what comes from without is not enough: they must have both origins, or they cannot make knowledge. "The conception," he says again, (ii. 221) "is not furnished by the mind till it has been furnished to the mind." But it is furnished to the mind by its own activity, operating according to its own laws. No doubt, the conception may be formed, and in cases of discovery, must be formed, by the suggestion and excitement which the facts themselves produce; and must be so moulded

as to agree with the facts. But this does not make it superfluous to examine, out of what *materials* such conceptions are formed, and *how* they are capable of being moulded so as to express laws of nature; especially, when we see how large a share this part of discovery—the examination how our ideas can be modified so as to agree with nature,—holds, in the history of science.

35 I have already (Art. 31) given, as evidence that the conception enters as an element in every induction, the constant introduction in such cases, of a new fixed term or phrase. Mr Mill (ii. 282) notices this introduction of a new phrase in such cases as important, though he does not appear willing to allow that it is necessary. Yet the necessity of the conception at least, appears to result from the considerations which he puts forward. “What darkness,” he says, “would have been spread over geometrical demonstration, if wherever the word *circle* is used, the definition of a circle was inserted instead of it.” “If we want to make a particular combination of ideas permanent in the mind, there is nothing which clenches it like a name specially devoted to express it.” In my view, the new conception is the *nail* which connects the previous notions, and the name, as Mr Mill says, *clenches* the junction.

36 I have above (Art. 33) referred to the difficulty of getting hold of the right conception, as a proof, that induction is not a mere juxtaposition of facts. Mr Mill does not dispute that it is often difficult to hit upon the right conception. He says (i. 360) "that a conception of the mind is introduced, is indeed most certain, and Mr Whewell has rightly stated elsewhere, that to hit upon the right conception is often a far more difficult, and more meritorious achievement, than to prove its applicability when obtained. But," he adds, "a conception implies and corresponds to something conceived; and although the conception itself is not in the facts, but in our mind, it must be a conception of something which really is in the facts." But to this I reply, that its being really in the facts, does not help us at all towards knowledge, if we cannot see it there. As the poet says,

It is the mind that sees: the outward eyes  
Present the object, but the mind descries.

And this is true of the sight which produces knowledge, as well as of the sight which produces pleasure and pain, which is referred to in the Tale.

37 Mr Mill puts his view, as opposed to mine, in various ways, but, as will easily be understood, the answers which I have to offer are in all cases nearly to the same effect.

Thus, he says (ii. 216), "the tardy development of several of the physical sciences, for example, of Optics, Electricity, Magnetism, and the higher generalizations of Chemistry, Mr Whewell ascribes to the fact that mankind had not yet possessed themselves of the idea of Polarity, that is, of opposite properties in opposite directions. But what was there to suggest such an idea, until by a separate examination of several of these different branches of knowledge it was shewn that the facts of each of them did present, in some instances at least, the curious phenomena of opposite properties in opposite directions?" But on this I observe, that these facts did not, nor do yet, present this conception to ordinary minds. The opposition of properties, and even the opposition of directions, which are thus apprehended by profound cultivators of science, are of an abstruse and recondite kind; and to conceive any one kind of polarity in its proper generality, is a process which few persons hitherto appear to have mastered; still less have men in general come to conceive of them all as modifications of a general notion of Polarity. The description which I have given of Polarity in general, "opposite properties in opposite directions," is of itself a very imperfect account of the manner in which corresponding antitheses are involved in the portions

of science into which Polar relations enter. In excuse of its imperfection, I may say, that I believe it is the first attempt to define Polarity in general; but yet, the conception of Polarity has certainly been strongly and effectively present in the minds of many of the sagacious men who have discovered and unravelled polar phenomena. They attempted to convey this conception, each in his own subject, sometimes by various and peculiar expressions, sometimes by imaginary mechanism by which the antithetical results were produced; their mode of expressing themselves being often defective or imperfect, often containing what was superfluous; and their meaning was commonly very imperfectly apprehended by most of their hearers and readers. But still, the conception was there, gradually working itself into clearness and distinctness, and in the mean time, directing their experiments, and forming an essential element of their discoveries. So far would it be from a sufficient statement of the case to say, that they conceived polarity because they saw it; —that they saw it as soon as it came into view; —and that they described it as they saw it.

38 The way in which such conceptions acquire clearness and distinctness is often by means of Discussions of Definitions. To define well a thought which already enters into

trains of discovery, is often a difficult matter. The business of such definition is a part of the business of discovery. These, and other remarks connected with these, which I had made in the *Philosophy*, Mr Mill has quoted and adopted (ii. 242). They appear to me to point very distinctly to the doctrine to which he refuses his assent,—that there is a special process in the mind, in addition to the mere observation of facts, which is necessary at every step in the progress of knowledge. The Conception must be *formed* before it can be *defined*. The Definition gives the last stamp of distinctness to the Conception; and enables us to express, in a compact and lucid form, the new scientific propositions into which the new Conception enters.

39 Since Mr Mill assents to so much of what has been said in the *Philosophy*, with regard to the process of scientific discovery, how, it may be asked, would he express these doctrines so as to exclude that which he thinks erroneous? If he objects to our saying that when we obtain a new inductive truth, we connect phenomena by applying to them a new Conception which fits them, in what terms would he describe the process? If he will not agree to say, that in order to discover the law of the facts, we must find an appropriate Conception, what language would he use instead

is this? This is a natural question; and the answer cannot fail to throw light on the relation in which his views and mine stand to each other.

Mr Mill would say, I believe, that when we obtain a new inductive law of facts, we find something in which the facts *resemble each other*; and that the business of making such discoveries is the business of discovering such resemblances. Thus, he says (of me,) (ii. 211), "his colligation of Facts by means of appropriate conceptions, is but the ordinary process of finding by a comparison of phenomena, in what consists their agreement or resemblance." And the Methods of experimental Inquiry which he gives (i. 450 &c.), proceed upon the supposition that the business of discovery may be thus more properly described.

40 There is no doubt that when we discover a law of nature by induction, we find some point in which all the particular facts agree. All the orbits of the planets agree in being ellipses, as Kepler discovered; all falling bodies agree in being acted on by a uniform force, as Galileo discovered; all refracted rays agree in having the sines of incidence and refraction in a constant ratio, as Snell discovered; all the bodies in the universe agree in attracting each other, as Newton discovered; all chemical compounds agree in being

constituted of elements in definite proportions, as Dalton discovered. But it appears to me a most scanty, vague, and incomplete account of these steps in science, to say that the authors of them discovered something in which the facts in each case agreed. The point in which the cases agree, is of the most diverse kind in the different cases—in some, a relation of space, in others, the action of a force, in others, the mode of composition of a substance;—and the point of agreement, visible to the discoverer alone, does not come even into his sight, till after the facts have been connected by thoughts of his own, and regarded in points of view in which he, by his mental acts, places them. It would seem to me not much more inappropriate to say, that an officer, who disciplines his men till they move together at the word of command, does so by finding something in which they agree. If the power of consentaneous motion did not exist in the individuals, he could not create it: but that power being there, he finds it and uses it. Of course I am aware that the parallel of the two cases is not exact; but in the one case, as in the other, that in which the particular things are found to agree, is something formed in the mind of him who brings the agreement into view.

41 But Mr Mill has not only thus de

scribed the business of scientific discovery; he has also given rules for it, founded on this description. It may be expected that we should bestow some attention upon the methods of inquiry which he thus proposes. I presume that they are regarded by his admirers as among the most valuable parts of his book; as certainly they cannot fail to be, if they describe methods of scientific inquiry in such a manner as to be of use to the enquirer.

Mr Mill enjoins four methods of experimental inquiry, which he calls *the Method of Agreement*, *the Method of Difference*, *the Method of Residues*, and *the Method of Concomitant Variations*. (B. III. c. viii.) They are all described by formulæ of this kind:—Let there be, in the observed facts, combinations of antecedents,  $ABC$ ,  $BC$ ,  $ADE$ , &c. and combinations of corresponding consequents,  $abc$ ,  $bc$ ,  $ade$ , &c.; and let the object of inquiry be, the consequence of some cause  $A$ , or the cause of some consequence  $a$ . The Method of Agreement teaches us, that when we find by experiment such facts as  $abc$  the consequent of  $ABC$ , and  $ade$  the consequent of  $ADE$ , then  $a$  is the consequent of  $A$ . The Method of Difference teaches us that when we find such facts as  $abc$  the consequent of  $ABC$ , and  $bc$  the consequent of  $BC$ , then  $a$  is the consequent of  $A$ . The Method of Residues, teaches us, that if  $abc$  be the

consequent of  $ABC$ , and if we have already ascertained that the effect of  $A$  is  $a$ , and the effect of  $B$  is  $b$ , then we may infer that the effect of  $C$  is  $c$ . The method of Concomitant Variations teaches us, that if a phenomenon  $a$  varies according as another phenomenon  $A$  varies, there is some connection of causation direct or indirect, between  $A$  and  $a$ .

42 Upon these methods, the obvious thing to remark is, that they take for granted, the very thing which is most difficult to discover, the reduction of the phenomena to formulæ such as are here presented to us. When we have any set of complex facts offered to us; for instance, those which were offered in the cases of discovery which I have mentioned,—the facts of the planetary paths, of falling bodies, of refracted rays, of cosmical motions, of chemical analysis; and when, in any of these cases, we would discover the law of nature which governs them, or, if any one chooses so to term it, the feature in which all the cases agree, where are we to look for our  $A, B, C$  and  $a, b, c$ ? Nature does not present to us the cases in this form; and how are we to reduce them to this form? You say, *when* we find the combination of  $ABC$  with  $abc$  and  $ABD$  with  $abd$ , then we may draw our inference. Granted: but when and where are we to find such combinations? Even now that the

discoveries are made, who will point out to us what are the *A, B, C*, and *a, b, c* elements of the cases which have just been enumerated? Who will tell us which of the methods of inquiry those historically real and successful inquiries exemplify? Who will carry these formulæ through the history of the sciences, as they have really grown up; and shew us that these four methods have been operative in their formation; or that any light is thrown upon the steps of their progress by reference to these formulæ?

43 Mr Mill's four methods have a great resemblance to Bacon's "Prerogatives of Instances;" for example, the Method of Agreement to the *Instantiæ Ostensivæ*; the Method of Differences to the *Instantiæ Absentiæ in Proximo*, and the *Instantiæ Crucis*; the Method of Concomitant Variations to the *Instantiæ Migrantes*. And with regard to the value of such methods, I believe all study of science will convince us more and more of the wisdom of the remarks which Sir John Herschel has made upon them (*Discourse*, Art. 192).

"It has always appeared to us, we must confess, that the help which the classification of instances under their different titles of prerogative, affords to inductions, however just such classification may be in itself, is yet more apparent than real. The force of the instance

must be felt in the mind before it can be referred to its place in the system; and before it can be either referred or appreciated, it must be known; and when it is appreciated we are ready enough to weave our web of induction, without greatly troubling ourselves whence it derives the weight we acknowledge it to have in our decisions. . . . No doubt instances as these are highly instructive; the difficulty in physics is to find such, not to perceive their force when found."

44 If Mr Mill's four methods had been applied by him in his book to a large body of conspicuous and undoubted examples of discovery, extending along the whole history of science, well selected and well analysed, they should have been better able to estimate the value of these methods. Mr Mill has certainly offered a number of examples of his method, but I hope I may say, without offense, that they appear to me to be wanting in the conditions which I have mentioned. As I have to justify myself for rejecting Mr Mill's criticism of the doctrines which I have put forward, and the examples which I have adduced, I may, I trust, be allowed to offer some critical remarks in my turn, bearing upon the examples which he has given, in order to illustrate his doctrines and precepts.

45 The first remark which I have

e is, that a large proportion of his examples 30, &c.) are taken from one favourite author; who, however great his merit may be, is so recent a writer to have had his discoveries confirmed by the corresponding investigations and searching criticisms of other writers in the same field, and placed in their proper and permanent relation to established truths; these alleged discoveries, e.g., at the same time, principally such as deal with the most complex and slippery portions of science, the laws of vital action. Thus Mill has adduced, as examples of discoveries, Prof. Liebig's doctrine—that death is produced by certain metallic poisons through their forming indecomposable compounds; the effect of respiration upon the blood consists in the conversion of peroxide of iron into protoxide—that the antiseptic power of oxygen arises from its attraction for moisture—that chemical action is contagious; and others. Now supposing that we have no doubt of the truth of these discoveries, we must still observe that they cannot wisely be referred to, in order to exemplify the nature of the progress of knowledge, till they have been verified by other chemists, and worked into their proper places in the general scheme of chemistry; especially, since it is tolerably certain that in the process of verification, they will

be modified and more precisely defined. Nor can I think it judicious to take so large proportion of our examples from a region of science in which, of all parts of our material knowledge, the conceptions both of ordinary persons and of men of science themselves, are the most loose and obscure, and the genuine principles most contested; which is the case in physiology. It would be easy, I think, to point out the vague and indeterminate character of many of the expressions in which the above examples are propounded, as well as their doubtful position in the scale of chemical generalization; but I have said enough to shew why I cannot give much weight to these, as cardinal examples of the method of discovery; and therefore I shall not examine in detail how far they support Mr Mill's methods of inquiry.

46 Mr Liebig supplies the first and majority of Mr Mill's examples in chapter of his Book on Induction. The second is an example for which Mr Mill states himself to be indebted to Mr Alexander Bain; the law established being this, that (i. 487) electricity can exist in one body without the simultaneous excitement of the opposite electricity in some neighbouring body, which Mr Mill also confirms by reference to Mr Faraday's experiments on voltaic wires.

I confess I am quite at a loss to understand what there is in the doctrine here ascribed to Mr Bain which was not known to the electricians who, from the time of Franklin, explained the phenomena of the Leyden vial. I may observe also that the mention of an "electrified atmosphere" implies a hypothesis long obsolete. The essential point in all those explanations was, that each electricity produced by induction the opposite electricity in neighbouring bodies, as I have tried to make apparent in the *History* (B. xi. c. xi.) Faraday has, more recently, illustrated this universal coexistence of opposite electricities with his usual felicity.

But the conjunction of this fact with voltaic phenomena, implies a non-recognition of some of the simplest doctrines of the subject. "Since," it is said, (i. 488) "common or machine electricity, and voltaic electricity may be considered for the present purpose to be identical, Faraday wished to know, &c." I think Mr Faraday would be much astonished to learn that he considered electricity in equilibrium, and electricity in the form of a voltaic current, to be, for any purpose, identical. Nor do I conceive that he would assent to the expression in the next page, that "from the nature of a voltaic charge, the two opposite currents necessary to the existence of each other are

both accommodated in one wire." Mr Faraday has, as it appears to me, studiously avoided assenting to this hypothesis.

47 The next example is the one already so copiously dwelt upon by Sir John Herschel, Dr Wells' researches on the production of Dew. I have already said (*Phil. B. xiii. c. ii. Art. 7*) that "this investigation, although it has sometimes been praised as an original discovery, was in fact only resolving the phenomenon into principles already discovered;" namely, the doctrine of a *constituent temperature* of vapour, the different conducting power of different bodies, and the like. And this agrees in substance with what Mr Mill says; (i. 497) that the discovery, when made, was corroborated by deduction from the known laws of aqueous vapour, of conduction, and the like. Dr Wells' researches on Dew tended much in this country to draw attention to the general principles of Atmology; and we may see, in this and in other examples which Mr Mill adduces, that the explanation of special phenomena by means of general principles already established, has, for common minds, a greater charm, and is more complacently dwelt on, than the discovery of the general principles themselves.

48 The next example, (i. 502) is given in order to illustrate the Method of Residues

d is the discovery by M. Arago that a disk of copper affects the vibrations of the magnetic needle. But this apparently detached fact affords little instruction compared with the regularly sagacious researches by which Mr Faraday discovered the cause of this effect to reside in the voltaic currents which the motion of the magnetic needle developed in the copper. I have spoken of this discovery in the *History of Science* (vol. xiii. c. viii.). Mr Mill however is quoting Mr John Herschel in thus illustrating the Method of Residues. He rightly gives the Perturbations of the Planets and Satellites as better examples of the method; (given also in the *Phil. Ind. Sc. B.* xiii. c. vii. § 17.)

49 In the next chapter (c. x.) Mr Mill speaks of Plurality of causes and of the Intermixture of effects, and gives examples of each case. He here teaches (i. 517) that chemical synthesis and analysis, (as when oxygen and hydrogen compose water, and when water is resolved into oxygen and hydrogen,) is properly *transformation*; but that because we find that the weight of the compound is equal to the sum of the weights of the elements, we take up the notion of chemical *composition*. I have endeavoured to shew (*Phil. Ind. Sc. B.* vi. c. iv.) that the maxim, that the sum of the weights of the elements is equal to the weight of the compound, was,

historically, not *proved* from experiment, but *assumed* in the reasonings upon experiments.

50 I have now made my remarks upon nearly all the examples which Mr Mill gives of scientific inquiry, so far as they consist of knowledge which has really been obtained. I may mention, as points which appear to me to interfere with the value of Mr Mill's references to examples, expressions which I cannot reconcile with just conceptions of scientific truth; as when he says (i. 523), "some other force which *impinges* on the first force;" and very frequently indeed, of the "*tangential force*," as co-ordinate with the centripetal force.

When he speaks (ii. 20, Note) of "the doctrine now universally received that the earth is a great natural magnet with two poles," he does not recognise the recent theory of Gauss, so remarkably coincident with a vast body of facts. (See *Hist. Ind. Sc.* B. XII. note (D) in the second edition.) Indeed in his statement, he rejects no less the earlier views proposed by Halley, theorized by Euler, and confirmed by Hansteen, which shew that we are compelled to assume at least *four* poles of terrestrial magnetism; which I had given an account of in the first edition of the *History*.

There are several other cases which he puts in which, the knowledge spoken of not having

seen yet acquired, he tells us how he would set about acquiring it; for instance, if the question were (i. 526) whether mercury be a cure for a given disease; or whether the brain be a voltaic pile (ii. 21); or whether the moon be inhabited (ii. 100); or whether all crows are black (ii. 124); I confess that I have no expectation of any advantage to philosophy from discussions of this kind.

51 I will add also, that I do not think any light can be thrown upon scientific methods, at present, by grouping along with such physical inquiries as I have been speaking of, speculations concerning the human mind, its qualities and operations. Thus he speaks (i. 508) of human characters, as exemplifying the effect of plurality of causes; of (i. 518) the phenomena of our mental nature, which are analogous to chemical rather than to dynamical phenomena; of (i. 518) the reason why susceptible persons are imaginative; to which I may add, the passage where he says (i. 444) "let us take as an example of a phenomenon which we have no means of fabricating artificially, a human mind." These, and other like examples, occur in the part of his work in which he is speaking of scientific inquiry in general, not in the Book on the Logic of the Moral Sciences; and are, I think, examples more likely to lead us astray

than to help our progress, in discovering the laws of Scientific Inquiry, in the ordinary sense of the term.

52 I will now pass from Mr Mill's methods, illustrated by such examples as those which I have been considering, to the views respecting the conditions of Scientific Induction to which I had been led, by such a survey as I could make, of the whole history of the principal Inductive Sciences; and especially, to those views to which Mr Mill offers his objections\*.

\* There are some points in my doctrines on the subject of the Classificatory Sciences, to which Mr. Mill objects; (ii. 314, &c.) but there is nothing which I think it necessary to remark here, except one point. After speaking of Classification of organised beings in general, Mr. Mill notices (ii. 321) as an additional subject, the arrangement of natural groups into a Natural Series; and he says, that "all who have attempted a theory of natural arrangement, including among the rest Mr. Whewell, have stopped short of this: all except M. Comte." On this I have to observe, that I stopped short of, or rather passed by, the doctrine of a Series of organized beings, because I thought it bad and narrow philosophy: and that I sufficiently indicated that I did this. In the *History* (B. xvi. c. vi.) I have spoken of the doctrine of Circular Progression propounded by Mr. Macleay, and have said, "so far as this view *negatives* a mere *linear* progression in nature, which would place each genus in contact with the preceding and succeeding ones, and so far as it requires us to attend to the more varied and ramified resemblances, there can be no doubt that it is supported by

Mr Mill thinks that I have been too favourable to the employment of hypotheses, as means of discovering scientific truth ; and that I have countenanced a laxness of method, in allowing hypotheses to be established, merely in virtue of the accordance of their results with the phenomena. I believe I should be as cautious as Mr Mill, in accepting mere hypothetical explanations of phenomena, in any case in which we had the phenomena, and their relations, placed before both of us in an equally clear light. I have not accepted the Undulatory theory of Heat, though recommended by so many coincidences and analogies (*Hist. Ind. Sc. B. x. Note (VA)* in the second edition). But I see some grave reasons for not giving any great weight to Mr Mill's admonitions ;—reasons drawn from the language which he uses on the subject, and which appears to me inconsistent with the conditions of the cases to which he applies it. Thus, when he says (ii. 22) that the condition of a hypothesis accounting for all the known phenomena is "often fulfilled equally well by two conflicting hypotheses," I can only say that I know of no such case in the history of Science,

the result of all the attempts to form natural systems." And with regard to the difference between Cuvier and M. de Blainville, to which Mr. Mill refers (ii. 321), I certainly cannot think that M. Comte's suffrage can add any weight to the opinion of either of those great naturalists.

where the phenomena are at all numerous and complicated ; and that if such a case were to occur, one of the hypotheses might always be resolved into the other. When he says that " this evidence (the agreement of the results of the hypothesis with the phenomena) cannot be of the smallest value, because we cannot have in the case of such an hypothesis the assurance that if the hypothesis be false it must lead to results at variance with the true facts," we must reply, with due submission, that we have, in the case spoken of, the most complete evidence of this ; for any change in the hypothesis would make it incapable of accounting for the facts. When he says that " if we give ourselves the license of inventing the causes as well as their laws, a person of fertile imagination might devise a hundred modes of accounting for any given fact ;" I reply, that the question is about accounting for a large and complex series of facts, of which the laws have been ascertained : and as a test of Mr Mill's assertion, I would propose as a challenge to any person of fertile imagination to devise any *one* other hypothesis to account for the perturbations of the moon, or the coloured fringes of shadows, besides the hypothesis by which they have actually been explained with such curious completeness. This challenge has been repeatedly offered, but never in any degree accepted ; and I

certain no apprehension that Mr Mill's proposition will ever be verified by such a performance.

53 I see additional reason for mistrusting the precision of Mr. Mill's views of that concordance of phenomena with the results of hypothesis, in several others of the expressions which he uses (ii. 23). He speaks of hypothesis being a "*plausible* explanation of all or most of the phenomena;" but the case which we have to consider is where it gives an *exact* representation of all the phenomena in which its results can be traced. He speaks of being certain that the laws of the phenomena are "*in some measure analogous*" to those given by the hypothesis; the case to be dealt with being, that they are in every way identical. He speaks of this analogy being certain, from the fact that the hypothesis can be "for a moment *tenable*;" as if any one had recommended a hypothesis which is tenable only while a small part of the facts are considered, when it is inconsistent with others which a fuller examination of the case discloses. I have nothing to say, and have said nothing, in favour of hypotheses which are *not* tenable. He says there are many such "*harmonies* running through the laws of phenomena in other respects radically distinct;" and he gives as an instance, the laws of light and heat. I have

never alleged such harmonies as grounds of theory, except they should amount to identities; and if they should do this, I have no doubt that the most sober thinkers will support the causes to be of the same kind in the two harmonizing instances. If chlorine, iodine and brome, or sulphur and phosphorus, have, as Mr. Mill says, analogous properties, I should call these substances *analogous*: but I can see no temptation to frame an hypothesis that they are *identical* (which he seems to fear), so long as Chemistry proves them distinct. But any hypothesis of an analogy in the constitution of these elements (suppose, for instance, a resemblance in their atomic form or composition) would seem to me to have a fair claim to trial, and to be capable of being elevated from one degree of probability to another by the number, variety, and exactitude of the explanation of phenomena which it should furnish.

54 These expressions of Mr. Mill have reference to a way in which hypotheses may be corroborated, in estimating the value of which, it appears that he and I differ. "It seems to be thought," he says (ii. 23), "that an hypothesis of the sort in question is entitled to a more favourable reception, if, besides a counting for the facts previously known, it has led to the anticipation and prediction of others which experience afterwards verified." An

adds, "Such predictions and their fulfilment are indeed well calculated to strike the ignorant vulgar;" but it is strange, he says,

any considerable stress should be laid on such a coincidence by scientific thinkers. However strange it may seem to him, there is no doubt that the most scientific thinkers, far more than the ignorant vulgar, have allowed the coincidence of results predicted by theory and fact afterwards observed, to produce the strongest effects upon their conviction; and that all the best-established theories have obtained their permanent place in general acceptance in virtue of such coincidences, more than any other evidence. It was not the ignorant vulgar alone, who were struck by the return of Halley's comet, as an evidence of Newtonian theory. Nor was it the ignorant vulgar, who were struck with those facts which did so much strike men of science, as famously felicitous proofs of the undulatory theory of light,—the production of darkness by two luminous rays interfering in a special manner; the refraction of a single ray of light into a conical pencil; and other complex and precise results, predicted by the theory and verified by experiment. It must, one would think, strike all persons in proportion to their thoughtfulness, that when Nature thus obeys our bidding, she acknowledges that we

have learnt her true language. If we can predict new facts which we have not seen, as well as explain those which we have seen, it must be because our explanation is not a mere formula of observed facts, but a truth of a deeper kind. Mr Mill says, "If the laws of the propagation of light agree with those of the vibrations of an elastic fluid in so many respects as is necessary to make the hypothesis a plausible explanation of all or most of the phenomena known at the time, it is nothing strange that they should accord with each other in one respect more." Nothing strange if the theory be true; but quite unaccountable if it be not. If I copy a long series of letters of which the last half-dozen are concealed, and if I guess those aright, as is found to be the case when they are afterwards uncovered, this must be because I have made out the import of the inscription. To say, that because I have copied all that I could see, it is nothing strange that I should guess those which I cannot see, would be absurd, without supposing such a ground for guessing. The notion that the discovery of the laws and causes of phenomena is a loose hap-hazard sort of guessing, which gives "plausible" explanations, accidental coincidences, casual "harmonies," laws, "in some measure analogous" to the true ones, suppositions "tenable" for a time, appears to me to

a misapprehension of the whole nature of science; as it certainly is inapplicable to the case to which it is principally applied by Mr Mill.

55 There is another kind of evidence of theories, very closely approaching to the verification of untried predictions, and to which, apparently, Mr Mill does not attach much importance, since he has borrowed the term by which I have described it, *Consilience*, but has applied it in a different manner (ii. 530, 563, 580). I have spoken, in the *Philosophy* (B. xi. c. v. art. 11), of the *Consilience of Inductions*, as one of the *Tests of Hypotheses*, and have exemplified it by many instances; for example, the theory of universal gravitation, obtained by induction from the motions of the planets, was found to explain also that peculiar motion of the spheroidal earth which produces the Precession of the Equinoxes. This, I have said, was a striking and surprising coincidence which gave the theory a stamp of truth beyond the power of ingenuity to counterfeit. I may compare such occurrences to a case of interpreting an unknown character, in which two different inscriptions, deciphered by different persons, should have given the same alphabet. We should, in such a case, believe with great confidence that the alphabet was the true one; and I will add, that I believe the history of

science offers no example in which a theory supported by such considerations, has been afterwards proved to be false.

56 Mr Mill accepts (ii. 21) a rule of Comte's, that we may apply hypotheses, provided they are capable of being afterwards verified as facts. I have a much higher respect for Mr Mill's opinion than for Comte's\*; but I do not think that this rule will be found of any value. It appears to me to be tainted with the vice which I have

\* I have given elsewhere (*Philos. Ind. Sc. B.* XII. c. 2) reasons why I cannot assign to M. Comte's *Philosophie positive* any great value as a contribution to the philosophy of science. In this judgment I conceive that I am supported by the best philosophers of our time. M. Comte owes much of the notice which has been given to him to his including, as Mr Mill does, the science of society and human nature in his scheme, and to his boldness in dealing with these. He appears to have been received with deference as a mathematician: but Sir John Herschel has shown that a supposed astronomical discovery of his is a mere assumption. I conceive that I have shewn that his representation of the history of science is erroneous, both in its details and in its generalities. His distinction of the three stages of sciences, the theological, metaphysical, and positive, is not all supported by the facts of scientific history. Real discoveries always involve what he calls *metaphysics*; and the doctrine of final causes in physiology, the main element of science which can properly be called *theological*, is retained to the end, as well as the beginning of the science, by all except a peculiar school.

ady noted, of throwing the whole burthen of  
 explanation upon the unexplained word *fact*—  
 explained in any permanent and definite  
 position to theory. As I have said, the  
 newtonian theory *is* a fact. Every true  
 theory is a fact. Nor does the distinction  
 become more clear by Mr Mill's examples.  
 The vortices of Descartes would have been,"  
 he says, "a perfectly legitimate hypothesis,  
 if it had been possible by any mode of  
 explanation which we could entertain the  
 hope of possessing, to bring the question  
 whether such vortices exist or not, within the  
 reach of our observing faculties." But this  
 was possible, and was done. The free pas-  
 sage of comets through the spaces in which  
 these vortices should have been, convinced  
 men that these vortices did not exist. In like  
 manner Mr Mill rejects the hypothesis of a  
 luminiferous ether, "because it can neither be  
 seen, heard, smelt, tasted, or touched." It is  
 a strange complaint to make of the vehicle of  
 light, that it cannot be heard, smelt, or tasted.  
 Its vibrations *can* be seen. The fringes of  
 shadows for instance, shew its vibrations, just  
 as the visible lines of waves near the shore  
 shew the undulations of the sea. Whether  
 this ether can be touched, that is, whether it  
 exists motion, is hardly yet clear. I am far  
 from saying there are not difficulties on this

point, with regard to *all* theories which suppose a *medium*. But there are no more difficulties of this kind in the undulatory theory of light, than there are in Fourier's theory of heat, which M. Comte adopts as a model of scientific investigation; or in the theory of voltaic *currents*, about which Mr Mill appears to have no doubt; or of electric *atmospheres* which, though generally obsolete, Mr Mill appears to favour; for though it had been said that we *feel* such atmospheres, no one had said that they have the other attributes of matter.

57 Mr Mill conceives (ii. 17) that his own rule concerning hypotheses coincides with Newton's Rule, that the cause assumed must be a *vera causa*. But he allows that "Mr Whewell... has had little difficulty in shewing that his (Newton's) conception was neither precise nor consistent with itself." He also allows that "Mr Whewell is clearly right in denying it to be necessary that the cause assigned should be a cause already known; else how could we ever become acquainted with new causes?" These points being agreed upon, I think that a little further consideration will lead to the conviction that Newton's Rule of philosophizing will best become a valuable guide, if we understand it as asserting that when the explanation of two or more different kinds of phenomena (as the revolutions of the

anets, the fall of a stone, and the precession of the equinoxes,) lead us to *the same* cause, which a coincidence gives a reality to the cause. We have, in fact, in such a case, a consilience of Inductions.

58 When Mr Mill condemns me (ii. 24) (using, however, expressions of civility which I gladly acknowledge,) for having recognized no mode of Induction except that of trying hypothesis after hypothesis until one is found which fits the phenomena, I must beg to remind the readers of our works, that Mr Mill himself allows (i. 363) that the process of finding a conception which binds together observed facts "is tentative, that it consists of succession of guesses, many being rejected until one at last occurs fit to be chosen."

I must remind them also that I have given Section upon the *Tests of Hypotheses*, to which I have just referred,—that I have given various methods of Induction, as the *Method of Gradation*, the *Method of Natural Classification*, the *Method of Curves*, the *Method of Means*, the *Method of Least Squares*, the *Method of Residues*: all which I have illustrated by conspicuous examples from the History of science; besides which, I conceive that what I have said of the Ideas belonging to each science, and of the construction and explication of conceptions, will point out in each case, in

what region we are to look for the Inductive Element in order to make new discoveries. I have already ventured to say, elsewhere, that the methods which I have given, are as definite and practical as any others which have been proposed, with the great additional advantage of being the method by which all great discoveries in science have really been made.

59 There is one feature in the construction of science which Mr Mill notices, but to which he does not ascribe, as I conceive, its due importance: I mean, that process by which we not only ascend from particular facts to a general law, but when this is done, ascend from the first general law to others more general; and so on, proceeding to the highest point of generalization. This character of the scientific process was first clearly pointed out by Bacon, and is one of the most noticeable instances of his philosophical sagacity. "There are," he says, "two ways, and can be only two, of seeking and finding truth. The one from sense and particulars, takes a flight to the most general axioms, and from these principles and their truth, settled once for all, invents and judges of intermediate axioms. The other method collects axioms from sense and particulars, ascending *continuously and by degrees*, so that in the end it

rives at the most general axioms :” meaning *axioms*, laws or principles. The structure of the most complete sciences consists of several such steps,—*floors*, as Bacon calls them, of successive generalization ; and thus this structure may be exhibited as a kind of scientific pyramid. I have constructed this pyramid in the case of the science of Astronomy\* : (*Phil. Ind. Sc. B. XI. c. vi.*) and I am gratified to find that the illustrious Humboldt approves of the design, and speaks of it as executed with complete success. (*Cosmos*, Vol. II. Note 5). The capability of being exhibited in this form of successive generalizations, arising from particulars upward to some very general law, is the condition of all tolerably perfect sciences ; and the steps of the successive generalizations are commonly the most important events in the history of the science.

60 Mr Mill does not reject this process of generalization ; but he gives it no conspicuous place, making it only one of three modes of reducing a law of causation into other laws. “There is,” he says, (i. 555) “the *absorption* of one law under another ; ... the gathering up of several laws into one more

\* I have also, in the same place, given the Inductive pyramid for the science of Optics. These Pyramids are necessarily inverted in their form, in order that, in reading the ordinary way, we may proceed to the vertex.

general law which includes them all." He adds afterwards, that the general law is the *sum* of the partial ones (i. 557), an expression which appears to me inadequate, for reasons which I have already stated. The general law is not the mere sum of the particular laws. It is, as I have already said, their amount *in a new point of view*. A new conception is introduced; thus, Newton did not merely add together the laws of the motions of the moon and of the planets, and of the satellites, and of the earth; he looked at them altogether as the result of a universal force of mutual gravitation; and therein consisted his generalization. And the like might be pointed out in other cases.

61 I am the more led to speak of Mr Mill as not having given due importance to this process of successive generalization, by the way in which he speaks in another place (ii. 525) of this doctrine of Bacon. He conceives Bacon "to have been radically wrong, when he enunciates, as a universal rule, that induction should proceed from the lowest to the middle principles, and from those to the highest, never reversing that order, and consequently, leaving no room for the discovery of new principles by way of deduction \* at all."

\* The reader will probably recollect that as *Induction* means the inference of general propositions from particular

62 I conceive that the Inductive Table of astronomy, to which I have already referred, shews that in that science, the most complete which has yet existed, the history of the science has gone on, as to its general movement, in accordance with the view which Bacon's sagacity enjoined. The successive generalizations, *so far as they were true*, were made by successive generations. I conceive also that the Inductive Table of Optics shews the same thing ; and this, without taking for granted the truth of the Undulatory Theory ; or with regard to all the steps of the progress of the science, lower than that highest one, there is, I conceive, no controversy.

63 Also, the Science of Mechanics, although Mr Mill more especially refers to it, is a case in which the highest generalizations (for example the Laws of Motion) were those earliest ascertained with any scientific exactness, will, I think, on a more careful examination of its history, be found remarkably to confirm Bacon's view. For, in that science, we have, in the first place, very conspicuous

cases, *Deduction* means the inference by the application of general propositions to particular cases, and by combining such applications ; as when from the most general principles of Geometry or of Mechanics, we prove some less general theorem ; for instance, the number of the possible regular solids, or the principle of *vis viva*.

examples of the vice of the method pursued by the ancients in flying to the highest generalizations first; as when they made their false distinctions of the laws of *natural* and *violent* motions, and of *terrestrial* and *celestial* motions. Many erroneous laws of motion were asserted through neglect of facts or want of experiments. And when Galileo and his school had in some measure succeeded in discovering some of the true laws of the motions of terrestrial bodies, they did not at once assert them as general: for they did not at all apply those laws to the celestial motions. As I have remarked, all Kepler's speculations respecting the causes of the motions of the planets, went upon the supposition that the First Law of terrestrial Motion did not apply to celestial bodies; but that, on the contrary, some continual force was requisite to keep up, as well as to originate, the planetary motions. Nor did Descartes, though he enunciated the Laws of Motion with more generality than his predecessors, (but not with exactness,) venture to trust the planets to those laws; on the contrary, he invented his machinery of Vortices in order to keep up the motions of the heavenly bodies. Newton was the first who extended the laws of terrestrial motion to the celestial spaces; and in doing so, he used all the laws of the celestial motions which had previously

been discovered by more limited inductions. To these instances, I may add the gradual generalization of the third Law of motion by Huyghens, the Bernoullis, and Herman, which I have described in the *History* (B. VI. c. v.) as preceding that Period of Deduction, to which the succeeding narrative (c. vi.) is appropriated. In Mechanics, then, we have a cardinal example of the historically gradual and successive ascent of science from particulars to the most general laws.

64 The Science of Hydrostatics may appear to offer a more favourable example of the ascent to the most general laws, without going through the intermediate particular laws; and it is true, with reference to this science, as I have observed (*Hist.* B. VI. c. vi. sect. 13), that it does exhibit the *peculiarity* of our possessing the most general principles on which the phenomena depend, and from which many cases of special facts are explained by deduction; while other cases cannot be so explained, from the want of principles intermediate between the highest and the lowest. And I have assigned, as the reason of this peculiarity, that the general principles of the Mechanics of Fluids were not obtained with reference to the science itself, but by extension from the sister science of the Mechanics of Solids. The two sciences are parts of the same Inductive

Pyramid; and having reached the summit of this Pyramid on one side, we are tempted to descend on the other from the highest generality to more narrow laws. Yet even in this science, the best part of our knowledge is mainly composed of inductive laws, obtained by inductive examination of particular classes of facts. The mere mathematical investigations of the laws of waves, for instance, have not led to any results so valuable as the experimental researches of Bremon tier, Emy, the Webers, and Mr Scott Russell. And in like manner in Acoustics, the Mechanics of Elastic Fluids, (*Hist. Ind. Sc. B. VIII.*), the deductions of mathematicians made on general principles have not done so much for our knowledge, as the cases of vibrations of plates and pipes examined experimentally by Chladni, Savart, Mr Wheatstone and Mr Willis. We see therefore, even in these sciences, no reason to slight the wisdom which exhorts us to ascend from particulars to intermediate laws, rather than to hope to deduce these latter better from the more general laws obtained once for all.

65 Mr Mill himself indeed, notwithstanding that he slights Bacon's injunction to seek knowledge by proceeding from less general to more general laws, has given a very good reason why this is commonly necessary and

ise. He says (ii. 526), "Before we attempt to explain deductively, from more general laws, any new class of phenomena, it is desirable to have gone as far as is practicable in ascertaining the empirical laws of these phenomena; so as to compare the results of induction, not with one individual instance after another, but with general propositions expressive of the points of agreement which have been found among many instances. For," he adds with great justice, "if Newton had been obliged to verify the theory of gravitation, not by deducing from it Kepler's laws, but by deducing all the observed planetary positions which had served Kepler to establish those laws, the Newtonian theory would probably never have emerged from the state of an hypothesis." To which we may add, that it is certain, from the history of the subject, that in that case the hypothesis would never have been framed at all.

66 Mr Mill expresses a hope of the efficacy of Deduction, rather than Induction, in promoting the future progress of Science; which hope, so far as the physical sciences are concerned, appears to me at variance with all the lessons of the history of those sciences. He says (i. 579), "that the advances henceforth to be expected even in physical, and still more mental and social science, will be chiefly the

result of deduction, is evident from the general considerations already adduced:” these considerations being, that the phenomena to be considered are very complex, and are the result of many known causes, of which we have to disentangle the results.

67 I cannot but take a very different view from this. I think that any one, looking at the state of physical science, will see that there are still a vast mass of cases, in which we do not at all know the causes, at least, in their full generality; and that the knowledge of new causes, and the generalization of the laws of those already known, can only be obtained by new *inductive* discoveries. Except by new Inductions, equal, in their efficacy for grouping together phenomena in new points of view, to any which have yet been performed in the history of science, how are we to solve such questions as those which, in the survey of what we already know, force themselves upon our minds. Such as, to take only a few of the most obvious examples—What is the nature of the connexion of heat and light? How does heat produce the expansion, liquefaction and vaporization of bodies? What is the nature of the connexion between the optical and the chemical properties of light? What is the relation between optical, crystalline and chemical po-

rity? What is the connexion between the  
 tomic constitution and the physical qualities  
 of bodies? What is the tenable definition of  
 mineral species? What is the true relation  
 of the apparently different types of vegetable  
 life (monocotyledons, dicotyledons, and crypto-  
 gamous plants)? What is the relation of the  
 various types of animal life (vertebrates, arti-  
 culates, radiates, &c.)? What is the number, and  
 what are the distinctions of the Vital Powers?  
 What is the internal constitution of the earth?  
 These, and many other questions of equal  
 interest, no one, I suppose, expects to see  
 solved by deduction from principles already  
 known. But we can, in many of them, see  
 good hope of progress by a large use of in-  
 duction; including, of course, copious and  
 careful experiments and observations.

68 With such questions before us, as have  
 now been suggested, I can see nothing but a  
 most mischievous narrowing of the field and  
 enfeebling of the spirit of scientific exertion,  
 in the doctrine that "Deduction is the great  
 scientific work of the present and of future  
 ages;" and that "A revolution is peaceably  
 and progressively effecting itself in philosophy  
 the reverse of that to which Bacon has at-  
 tached his name." I trust, on the contrary,  
 that we have yet many new laws of nature  
 still to discover; and that our race is destined

to obtain a sight of wider truths than any yet discern, including, as cases, the general laws we now know, and obtained from the known laws as they must be, by Induction.

69 I can see, however, reasons for comparatively greater favour with which Mill looks upon Deduction, in the views which he has mainly directed his attention. The explanation of remarkable phenomena known laws of Nature, has, as I have already said, a greater charm for many minds than the discovery of the laws themselves. In the case of such explanations, the problem proposed is more definite, and the solution more obviously complete. For the process of induction includes a mysterious step, by which we pass from particulars to generals, of which the reason always seems to be inadequately rendered by any words which we can use; and this step to most minds is not demonstrable, as to few is it given to perform it on a grand scale. But the process of explanation of facts by known laws is deductive, and has at every step a force like that of demonstration, producing a feeling peculiarly gratifying to clear intellects which are most capable of following the process. We may often see instances in which this admiration for deductive science appears in an extravagant measure; as when men compare Laplace with Newton.

Should I think it my business to argue against such a preference, except it were likely to leave us too well satisfied with what we know already, to chill our hope of scientific progress, and to prevent our making any further strenuous efforts to ascend, higher than we have yet done, the mountain-chain which limits human knowledge.

70 But there is another reason which, I conceive, operates in leading Mr Mill to look to Deduction as the principal means of future progress in knowledge, and which is a reason of considerable weight, in the subjects of research which, as I conceive, he mainly has in view. In the study of our own minds and of the laws which govern the history of society, I do not think that it is very likely that we shall hereafter arrive at any wider principles than those of which we already possess some considerable knowledge; and this, for a special reason; namely, that our knowledge in such cases is not gathered by mere external observation of a collection of external facts; but acquired by attention to internal facts, our own emotions, thoughts, and springs of action; facts which are connected by ties existing in our own consciousness, and not in mere observed juxta-position, succession, or similitude. How the character, for instance, is influenced by various causes, (an example to which Mr Mill repeatedly refers, ii. 518, &c.), is an enquiry

which may perhaps be best conducted by considering what we know of the influence of education and habit, government and opinion, hope and fear, vanity and pride, and the like, upon men's characters, and by tracing the various effects of the intermixture of influences. Yet even here, there seems room for the discovery of laws in the experimental inquiry: for instance, what race or family has in the formation of character; a question which can hardly be solved to any purpose in any other way than collecting and classing instances. And in the same way, many of the principles which regulate the material wealth of states, are obtained if not exclusively, at least most clearly and securely, by induction from large series of facts. Still, however, I am quite ready to say that in Mental and Social Science, we are less likely than in Physical Science, to discover new truths by any process which can be distinctly termed *Induction*; and that in the sciences, what may be called *Deductions* from principles of thought and action of which we are already conscious, or to which we are drawn when they are felicitously picked out from our thoughts and put into words, must have a large share; and I may add, that this observation of Mr Mill appears to me to be important in its present connexion, new.

71 I have made nearly all the re

which I now think it of any consequence to make upon Mr Mill's *Logic*, so far as it bears upon the doctrines contained in my *History and Philosophy*. And yet there remains still untouched one great question, involving probably the widest of all the differences between me and me. I mean the question whether geometrical axioms (and, as similar in their evidence to these, *all* axioms) be truths derived from experience, or be necessary truths in some deeper sense. This is one of the fundamental questions of philosophy; and all persons who take an interest in metaphysical discussions, know that the two opposite opinions have been maintained with great zeal in all ages of speculation. To me it appears that there are *two* distinct elements in our knowledge, Experience, without, and the Mind, within. Mr Mill derives all our knowledge from Experience *one*. In a question thus going to the root of all knowledge, the opposite arguments must needs cut deep on both sides. Mr Mill cannot deny that our knowledge of geometrical axioms and the like, *seems* to be *necessary*. I cannot deny that our knowledge, axiomatic as well as other, *never is* acquired *without experience*.

72 Perhaps ordinary readers may despair of following our reasonings, when they find that they can only be made intelligible by supposing, on the one hand, a person who thinks dis-

tinctly, and yet has never seen or felt any ternal object; and on the other hand, a person who is transferred, as Mr Mill supposes (ii. 1) to "distant parts of the stellar regions where the phenomena may be entirely unlike those with which we are acquainted," and where even the axiom, that every effect must have a cause, does not hold good. Nor, in truth, do I think it necessary here to spend many words on this subject. Probably, for those who have an interest in this discussion, most of the arguments on each side have already been set forwards with sufficient repetition. I have done so in an "Essay on the Fundamental Antitheses of Philosophy," and in some accompanying "Remarks," printed at the end of the second edition of my *Philosophy*, given my reply to what has been said on this subject, both by Mr Mill, and by the author of a very able critique on my *History and Philosophy* which appeared in the *Quarterly Review* in 1841, and I will not here attempt to revive a general discussion.

73 Perhaps I may be allowed to note that in one part of Mr Mill's work where this subject is treated, there is the appearance of one of the parties to the controversy pronouncing judgment in his own cause. This is indeed a temptation which it is especially difficult for an author to resist, who writes

atise upon *Fallacies*, the subject of Mr Mill's h Book. In such a treatise, the writer has easy way of disposing of adverse opinions classing them as "Fallacies," and putting m side by side with opinions universally knowledged to be false. In this way, Mr ll has dealt with several points which are l, as I conceive, matters of controversy. 357, &c.).

74 But undoubtedly, Mr Mill has given argument against my opinions with great tinctness in another place (i. 319). In order shew that it is merely habitual association ch gives to an experimental truth the racter of a necessary truth, he quotes the e of the laws of motion, which were really covered from experiment, but are now ked upon as the only conceivable laws; l especially, what he conceives as "the *ratio ad absurdum* of the theory of inconceiv- eness," an opinion which I had ventured to ow out, that if we could conceive the Com- ition of bodies distinctly, we might be able ee that it is necessary that the modes of ir composition should be definite. I do not k that readers in general will see anything urd in the opinion, that the laws of Mecha- s, and even the laws of the chemical Com- ition of bodies, may depend upon princi- s as necessary as the properties of space

and number; and that this necessity, not at all perceived by persons who only the ordinary obscure and confused on such subjects, may be evident to which has, by effort and discipline, its ideas of Mechanical Causation, Elements of Composition and Difference of Kinematics, and precise. It may easily be, I conceive, that while such necessary principles are perceived to be necessary only by a few of highly cultivated insight, such principles the axioms of Geometry and Arithmetics be perceived to be necessary by all which have any habit of abstract thought: and I conceive also, that though axioms are brought into distinct view, a certain degree of intellectual cultivation they may still be much better descriptions of conditions of experience, than as representations of experience:—as laws of the mind and activity, rather than as facts impressed on a mind merely passive.

75 I will not pursue the subject only, as the question has arisen respecting absurdities to which each of the doctrines leads, I will point out opinions connected with this subject, which Mr. Hume stated in various parts of his book.

He holds (i. 317) that it is merely a habit that we are unable to conceive

vint of space or the *last instant* of time. He holds (ii. 360) that it is strange that any one would rely upon the *à priori* evidence that space or extension is infinite, or that nothing can be made of nothing. He holds (i. 304) that the first law of *motion* is *rigorously* true, but that the axioms respecting the *lever* are only *approximately* true. He holds (ii. 110) that there may be sidereal firmaments in which events succeed each other at random, without obeying any laws of causation; although one might suppose that even if space and cause are both to have their limits, still they might terminate together: and then, even on this bold supposition, we should nowhere have a world in which events were usual. He holds (ii. 111) that the axiom, that every event must have a cause, is established by means of an "induction by simple enumeration:" and in like manner, that the principles of number and of geometry are proved by this method of simple enumeration alone. He ascribes the proof (i. 162) of the axiom, "things which are equal to the same are equal to each other," to the fact that this proposition has been perpetually *found* true and never false. He holds (i. 338) that "In all propositions concerning numbers, a condition is implied, without which none of them would be true; and that condition is an assumption which may be false. The condition is that  $1 = 1$ ."

76 Mr Mill further holds (i. 309), that it is a characteristic property of geometrical forms, that they are capable of being painted in the imagination with a distinctness equal to reality:—that our ideas of forms exactly resemble our sensations; which, it is implied, is not the case with regard to any other class of our ideas;—that we thus may have mental pictures of all possible combinations of lines and angles, which are as fit subjects of “geometrical experimentation” as the realities themselves. He says, that “we know that the imaginary lines exactly resemble real ones;” and that we obtain this knowledge respecting the characteristic property of the idea of space by experience; though it does not appear *how* we can compare our *ideas* with the *realities*, since we know the realities only *by* our ideas; or why this property of their resemblance should be confined to *one class* of ideas alone.

77 I have now made such remarks as appear to me to be necessary, on the most important parts of Mr Mill’s criticism of my *Philosophy*. I hope I have avoided urging any thing in a contentious manner; as I have certainly written with no desire for controversy, but only with a view to offer to those who may be willing to receive it, some explanation of portions of my previous writings. I have already said, that if this had not been my especial object, I could with pleasure have noted

the passages of Mr Mill's *Logic* which I admire, rather than the points in which we differ. I will in a very few words refer to some of these points, as the most agreeable way of taking leave of the dispute.

I say then that Mr Mill appears to me especially instructive in his discussion of the nature of the proof which is conveyed by the syllogism; and that his doctrine, that the force of the syllogism consists in an *inductive assertion, with an interpretation added to it*, solves very happily the difficulties which baffle the other theories of this subject. I think that this doctrine of his is made still more instructive, by his excepting from it the cases of Scriptural Theology and of Positive Law (i. 260), as cases in which general propositions, not particular facts, are our original data. I consider also that the recognition of *Kinds* (i. 166) as classes in which we have, not a finite but an *inexhaustible* body of resemblances among individuals, and as groups made by nature, not by mere definition, is very valuable, as stopping the inroad to an endless train of false philosophy. I conceive that he takes the right ground in his answer to Hume's argument against miracles (ii. 183): and I admire the acuteness with which he has criticized Laplace's tenets on the Doctrine of Chances, and the candour with which he has, in the second edition, acknow-

ledged oversights on this subject made in the first. I think that much, I may almost say, which he says on the subject of Language is very philosophical; for instance, what he says (ii. 238) of the way in which words acquire their meaning in common use. I especially admire the acuteness and force with which he has shewn (ii. 255) how moral principles expressed in words degenerate into formulae and yet how the formula cannot be rejected without a moral loss. This "perpetual relation in spiritual truths," as he happily terms it, has never, I think, been noted in the same broad manner, and is a subject of most instructive contemplation. And though I myself refrained from associating moral and political with physical science in my study of the subject, I see a great deal which is fit to promise for the future progress of moral and political knowledge in Mr Mill's sixth Essay, "On the Logic of the Moral and Political Sciences." Even his arrangement of the various methods which have been or may be followed in "the Social Science,"—"the Chemical Experimental Method," "the Geometrical Abstract Method," "the Physical or Concrete Deductive Method," "the Inverse Deductive or Historical Method," though in some details fanciful and forced, abounds with valuable suggestions; and his estimate of "the inter-

ing philosophy of the Bentham school," the main example of "the geometrical method," is interesting and philosophical. On some future occasion, I may, perhaps, venture into the region of which Mr Mill has thus essayed to map the high ways: for it is from no despair either of the great progress to be made in such truths as that here referred to, or of the effect of philosophical method in arriving at such truth, that I have, in what I have now written, confined myself to the less captivating but more definite part of the subject.

*C. C., June 27, 1849.*

THE END.

# NEW BOOKS AND NEW EDITIONS,

PUBLISHED BY

JOHN W. PARKER, WEST STRAND.

---

**The Holy City: Historical, Topographical, and Antiquarian Notices of Jerusalem.** By **GEORGE WILLIAMS, B.D.**, Fellow of King's College, Cambridge. Second Edition, with considerable additions, including

**THE ARCHITECTURAL HISTORY OF THE HOLY SEPULCHRE,**

By **PROFESSOR WILLIS.**

With this Edition is also published

**A PLAN OF THE TOWN & ENVIRONS OF JERUSALEM,**

copied, by permission of Field-Marshal the **MARQUIS OF ANGLESEY**, from the Original Drawing of the Survey made by Lieutenants **ALDRICH** and **SYMONDS**, of the Royal Engineers, under the orders of Lieut. Colonel **ANDERSON**, Commanding the Royal Engineers in Syria. 2 large vols. octavo, with Illustrations. 2*l.* 5*s.*

\*.\* The Survey, of which this is a copy, is the only one that has ever been made by professional Surveyors, and is beautifully engraved by Mr. **LOWRY**. The forms of the mountains and valleys are for the first time rendered with the accuracy of a model from the contour lines of the original Drawings.

THE PLAN, with an **HISTORICAL AND DESCRIPTIVE MEMOIR**, reprinted from Williams's *Holy City*, may be had separately, price 9*s.*; and also Mounted on Canvas, with Rollers, for use in Libraries, Schools, &c., price 18*s.*

**The Architectural History of the Holy Sepulchre.**

By **PROFESSOR WILLIS**. Reprinted from the above work. Octavo, illustrated by Engravings from Drawings never before published. 9*s.*

---

**On the Influence of Authority in Matters of Opinion.** By **G. CORNEWALL LEWIS, Esq., M.P.** Octavo. 10*s.* 6*d.*

---

**Wales: the Language, Social Condition, Moral Character, and Religious Opinions of the People, considered in their Relation to Education.** By **SIR THOMAS PHILLIPS**. Octavo. 14*s.*

*New Books and New Editions,*

---

**The Colonies of England: a Plan for the Government of Some Portion of our Colonial Possessions.** By J. A. ROEBUCK, M.P. Octavo, with Map, 7s. 6d.

---

**A View of the Art of Colonization; with Present Reference to the British Empire. In Letters between a Statesman and a Colonist.** Edited by (One of the Writers) EDWARD GIBBON WAKEFIELD. Octavo, 12s.

---

**The Evils of England, Social and Economical.** By A LONDON PHYSICIAN. 2s. 6d.

---

THE INTRODUCTORY LECTURES DELIVERED AT  
**QUEEN'S COLLEGE, LONDON,**  
BY

W. S. BENNETT,	Rev. S. CLARK,	Rev. C. KINGSLEY,
Dr. BROLCHI,	Prof. HALL,	Prof. MAURICE,
Prof. BERNAYS,	JOHN HULLAH,	Rev. C. G. NICOLAY,
Prof. BRASSEUR,	Rev. T. JACKSON,	Prof. O'BRIEN,
Rev. A. B. STRETTILL, and HENRY WARREN.		

Foolscap Octavo, 5s.

---

**Minerals and their Uses.** In a Series of Letters to a Lady. By J. R. JACKSON, F.R.S. With a coloured Frontispiece. 7s. 6d.

---

**The Hand-Book for New Zealand.** The most recent Information compiled for the Use of Intending Colonists. By A LATE MAGISTRATE OF THE TERRITORY. 6s.

---

**Wild Life in the Interior of Central America.** By G. BYAM, late 43rd Light Infantry. With Frontispiece, 5s.

---

**English Life, Social and Domestic, in the Middle of the Nineteenth Century, considered in Reference to our Position as a Community of Professing Christians.** 4s. 6d.

*Published by John W. Parker, West Strand.*

---

**Journal of Summer Time in the Country.**

By R. A. WILLMOTT, Incumbent of Bear Wood. 5s.

---

**Parish Sermons. By JULIUS CHARLES HARE,**

M.A., Archdeacon of Lewes. The Second Series. Octavo, 12s.

---

**Sacred Latin Poetry, selected and arranged**

for use; with Notes and Introduction by R. C. TRENCH, M.A.,  
Examining Chaplain to the Lord Bishop of Oxford. Foolscap  
octavo, 7s.; or 14s. bound in antique calf.

---

**Twenty-Five Village Sermons. By CHARLES**

KINGSLEY, jun., Rector of Eversley. 5s.

---

**The Lord's Prayer: Nine Sermons, preached**

in the Chapel of Lincoln's Inn. By F. D. MAURICE, M.A.,  
Professor of Divinity in King's College, London. 2s. 6d.

---

**What has Religion to do with Politics? By**

D. R. MORIER, Esq., late Her Majesty's Minister Plenipoten-  
tiary in Switzerland. 2s. 6d.

---

**Burnet's History of the Reformation of the**

Church of England, Abridged. By G. E. CORRIE, B.D., Norri-  
sian Professor of Divinity, Cambridge. Octavo. 10s. 6d.

In this Edition the Supplemental Matter added by the Bishop, and which  
has hitherto existed in a separate form, has been incorporated into the  
History; admitted Errors have been corrected; and some Changes and  
Additions made.

---

**A History of the English Reformation. By**

F. C. MASSINGBERD, M.A., Rector of South Ormsby. A New  
Edition, Revised and Enlarged. 6s.

*New Books and New Editions,*

---

**Elements of Logic.** By R. WHATELY, D.D.,  
Archbishop of Dublin. Ninth (octavo) Edition. 10s. 6d.

---

**A System of Logic: Ratiocinative and Inductive.** By JOHN STUART MILL. Second Edition, two volumes, octavo. 30s.

---

**Elements of Rhetoric.** By R. WHATELY, D.D.,  
Archbishop of Dublin. Seventh Edition. 10s. 6d.

---

**Elements of Morality, including Polity.** By  
W. WHEWELL, D.D., Master of Trinity College, Cambridge.  
New Edition, reduced in size and price. Two Volumes. 15s.

---

**Lectures on Systematic Morality, delivered**  
before the University of Cambridge. By the same Author.  
Octavo. 7s. 6d.

---

**Sterling's Essays and Tales.** Collected and  
Edited, with a Sketch of the Author's Life. By JULIUS CHARLES  
HARR, M.A., Rector of Herstmonceux. Two volumes, post  
octavo, with a Portrait. 21s.

---

**The Statutes relating to the Ecclesiastical**  
and Eleemosynary Institutions of England, Ireland, India, and  
the Colonies: with the Decisions thereon. By A. J. STEPHENS,  
M.A., F.R.S. Two volumes, royal octavo. 3l. 3s. boards;  
3l. 13s. 6d. in law calf.

---

**Indications of the Creator: Theological Ex-**  
tracts from the HISTORY AND PHILOSOPHY OF THE INDUCTIVE  
SCIENCES. By W. WHEWELL, D.D. Second Edition. 5s. 6d.

*Published by John W. Parker, West Strand.*

---

**Mission of the Comforter, and other Sermons.**

With Notes. By JULIUS CHARLES HARE, M.A., Archdeacon of Lewes. Two volumes, octavo. 25s.

---

**Christmas Day, and other Sermons. By F. D.**

MAURICE, M.A., Professor of Divinity in King's College. 10s. 6d.

---

**College Chapel Sermons. By W. WHEWELL,**

D.D., Member of Trinity College, Cambridge. Octavo. 10s. 6d.

---

**Sermons preached before the University of**

Oxford. By C. A. OGILVIE, D.D., Regius Professor of Pastoral Theology. Octavo. 5s.

---

**Lectures on the Epistle to the Hebrews, with**

a Review of Mr. Newman's Theory of Development. By F. D. MAURICE, M.A. 7s. 6d.

---

**Lectures on the Prophecies. By A. MAC CAUL,**

D.D., Professor of Divinity in King's College, London. Octavo. 7s.

---

**The Victory of Faith. By ARCHDEACON HARE.**

Second Edition. 6s.

---

**The Religions of the World, and their Rela-**

tions to Christianity. By F. D. MAURICE, M.A., Professor of Divinity in King's College, London. Second Edition, reduced in size and price. 5s.

---

**Book of Common Prayer in Latin.**

Liber Precum Publicarum; ordo Administrandæ Cœnæ Domini, Catechismus, Ecclesiæ Anglicanæ. Psalterium. Royal 24mo, printed with red border lines, 5s. 6d. cloth; 10s. 6d. in antique calf, red edges.

*New Books and New Editions,*

---

**Principles of Political Economy, with some of their Applications to Social Philosophy.** By JOHN STUART MILL. Second Edition. Two volumes, octavo. 30s.

**Essays on Political Economy.** By the same Author. Octavo. 6s. 6d.

---

**History of the Royal Society.** Compiled from Original Authentic Documents. By C. R. WELD, Assistant-Secretary to the Royal Society. Two volumes, octavo. 30s.

---

**Philosophy of the Inductive Sciences.** By WILLIAM WHEWELL, D.D., F.R.S., Master of Trinity College, Cambridge. A New Edition, Revised. Two volumes, octavo. 30s.

**History of the Inductive Sciences.** By the same Author. A New Edition. Three volumes. 2l. 2s.

---

**A Manual of Chemistry.** By WILLIAM THOMAS BRANDE, F.R.S., Professor at the Royal Institution. The Sixth Edition, almost wholly re-written, considerably enlarged, and embodying all the recent Discoveries in the Science up to the present time. Two volumes, octavo. 2l. 5s.

---

**An Introduction to the Study of Chemical Philosophy.** By the late PROFESSOR J. F. DANIELL, F.R.S. With numerous Illustrations. The Second Edition. 2l.

**Elements of Meteorology.** Two volumes, octavo, with Plates and Coloured Charts. By the same Author. 32s.

---

**A Cycle of Celestial Objects.** By CAPTAIN W. H. SMYTH, R.N., K.S.F., D.C.L., F.R.S., President of the Astronomical Society. Two volumes, octavo, with Illustrations. 2l. 2s.

---

**Physiological Anatomy and Physiology of Man.** With numerous original Illustrations. By R. B. TODD, M.D., F.R.S., and W. BOWMAN, F.R.S., King's College, London. Volume I. in cloth, 15s. Parts 2 and 3, 7s. each.

*Published by John W. Parker, West Strand.*

---

**C. Cornelii Taciti Opera. Ad Codices antiquos exacta et emendata, Commentario exegetico illustrata.** Edidit FRANCISCUS RITTER, Westfalus Professor Bonnensis. Complete in Four Volumes. Octavo. 28s.

---

**The Antigone of Sophocles, in Greek and English, with Critical and Explanatory Notes.** By J. W. DONALDSON, D.D., Head Master of King Edward the Sixth's School, Bury St. Edmunds. Octavo. 9s.

---

**The Agamemnon of Æschylus, the Greek Text, with a Translation into English Verse, and Notes, Critical and Explanatory.** By JOHN CONINGTON, B.A., Fellow of University College, Oxford. Octavo. 7s. 6d.

---

**The Phædrus, Lysis, and Protagoras of Plato.** A new and literal Translation, mainly from the Text of Bekker. By J. WRIGHT, B.A., Head Master of Sutton Coldfield Grammar School. 4s. 6d.

---

**Arundines Cami; sive Musarum Cantabrigiensium Lusus Canori.** Collegit atque edidit HENRICUS DRURY, A.M. Third Edition, Revised and Enlarged. Octavo. 12s.

---

**A Lexicon of the Hebrew Language.** With a Hebrew Grammar, Vocabulary, and Grammatical Analysis of the Book of Genesis. Also, a Chaldee Grammar, Lexicon, and Grammatical Analysis of the Old Testament. By the REV. T. JARRETT, M.A., Professor of Arabic, Cambridge. Octavo. 21s.

---

**The Psalms in Hebrew, with a Critical, Exegetical, and Philological Commentary, intended for the use of Students.** By G. PHILLIPS, B.D., Fellow and Tutor of King's College, Cambridge. Two volumes, octavo. 32s.

*New Books and New Editions.*

---

**The Saint's Tragedy: the True Story of Elizabeth of Hungary.** By C. KINGSLEY, Jun., Rector of Eversley. Edited, with Preface, by PROFESSOR MAURICE. 6s.

---

**A Familiar History of Birds.** By the late E. STANLEY, D.D., F.R.S., Lord Bishop of Norwich. Fourth Edition, with Additions. 3s.

---

**Six Dramas Illustrative of German Life; from the original of PRINCESS AMALIE of Saxony.** With Illustrations. 10s. 6d.

---

**Readings from Shakspeare, in illustration of his Characters.** For use in schools and families. Edited by the Author of "Aids to Development." 4s. 6d.

---

**Student's Manual of Ancient History.** By the late W. C. TAYLOR, LL.D. Fifth Edition. 10s. 6d.

**The Student's Manual of Modern History.** By the same Author. Fourth Edition. 10s. 6d.

---

**Becker's Gallus; or, Roman Scenes of the Time of Augustus, with Notes and Excursus illustrative of the Manners and Customs of the Romans.** Second Edition, enlarged.

**Becker's Charicles; or, Illustrations of the Private Life of the Ancient Greeks.**

Translated by the REV. F. METCALFE, M.A., Fellow of Lincoln College, Oxford.

Post octavo, with Illustrations. 12s. each.

---

**Travels in the Track of the Ten Thousand Greeks: a Geographical and Descriptive Account of the Expedition of Cyrus, and of the Retreat of the Ten Thousand, as related by Xenophon.** By W. F. AINSWORTH, F.G.S. 7s. 6d.
